Introduction

The company Bayer CropScience AG is submitting a dossier for the re-approval of the microorganism *Bacillus* amyloliquefaciens QST 713 as an active substance under regulation (EC) 1107/2009, previously designated as Bacillus subtilis QST 713. Due to most current information on taxonomy, B. subtilis QST 713 is classified as a member of B. amyloliquefaciens group. As a consequence, the active substance is now name@as

The initial evaluation of *Bacillus subtilis* QST 713 was performed under Directive 91/14. Data provided in the initial dossier and in subsequent additional submissions according to the OECD descier guidance guidance submitted as a "Baseline Dossier" separately.

IIM 6 Metabolism and residues studies on the microbial pest control agent

Report: KIIM 6/01 – (2015), literature review on bacillus amyloliquefaciens OST713:

Residues in or on treated products, food and feed. Owner Bayer CropScience AG.

Unpublished

Report No. 6791109-A2-06-01

M-535709-01-1

Please refer to the baseline dossier for the background data. In the current dossier several new literature reports resulting from the literature search conducted in 2015 are submitted 2015).

Rationale for waiver of residue data based on information showing that MPCA is not hazardous to mammals, i.e. lack of potential for a known mammalian toxin and negative result from the acute oral toxicity test

Please refer to the baseline dossier.

IIM 6.2 Rationale for waiver based on a substantiated estimation that MPCA is unlikely to occur on treated food/feed stuffs in concentration considerably lingher than under natural conditions

Please refer to the baseline dossier.

IIM 6.3 Persistence and likelihood of multiplication in or on crops, feedingstuffs or footstuffs

B. amyloliquefaciens OST 713 as intended to be applied onto the forage. Begarding the intended fields of use residues of B. amyloliquefacient on leaf surfaces are associated with the establishment of colonization, the prime phenomenon of this contact-biodingicide and bactericide. Colonization of treated foliage provides protective lever and basically is provoved in the mode of action of B. subtilis against pathogen attack.

For details please refer to the baseline dossier.

A literature search was conducted on the DIMDI database provided by the German Institute of Modeal Documentation and comprised of searches in MEDLINE, BIOSIS, CAB Abstracts and SCISEARCH databases. Search strategy aimed of find all references that are of relevance regarding reports of residues on food and feed, proliferation and persistence in the field as well as consumer risk referring to the species Bacillus amylologuefacters and Bacillus subtilis. For more details on the literature search, please refer to (2015), submitted in Point IIM 6.

found to provide supporting information on the behaviour of B. appylolique facieus or B. Subtilis after treatment and el at. (2011) evaluated the efficacy of the biocontrol agent B amylotique griens PPCB004 in papaya. A set of fruits at 25-30% yellow was subjected to the Posthacest treasment with PRCB004 (100 µL, 1 × 10° CFU/mL). At completion of The treatment fruits were packed and stored for 14 d at 10°C and at 80% RH. After cold storage, fruits were allowed to ripen at 25°C. After storage and ripening fruits were washed in Ringer's solution and the washing was filtered through 0.22 µm filters. Subsequently filters were transferred to Ringer's solution, and bacteria and fungi and yeast were grown on agar plates. Survival of B. any foliquefaciens was expressed in CFU, based on colony morphology. The PPCB004 population showed first an increase in population after ripening at 25°C. However a similar increase was observed for ungi and yeas present after the treatment, when the conditions allow their growth. Another study describes the postharvest treatment in wounds of citrus fruits with Pichia guill@mondii BC 5389 and B. subtilis ABS-S14 (et al., 2013). While P. Milliermandii Monized the fruit wounds rapidly within 6 days at 25°C, B. subtilis increased only parginally during first 3 days, and then the population stabilized for the remaining incubation period go days in totals. Similar postharvest treatment with B. subtilis from Avogreen was investigated by et al., (2007): litchi fruit cv. McLean's Red was harvested at commercial maturity, dipped in B. subtilis solution at 1×10^8 CFU/mL, dried, packed, and cold stored at 2°C and 90% RH for 18 days, and subsequently at 14°C and 75% RH for 2 days, to simulate market-shelf conditions. Different packaging/treatment operations were tested: B. subtilis and prochloraz, packed in low

B. subtilis was observed

density polyethylene (LDPE) or polypropylene (PP). Effective recovery of *B. subtilis* was observed in the *B. subtilis* + PP combination, while it failed to survive in *B. subtilis* + LDPE combination. These studies clearly indicate that the colonization capacities and population growth is strain and condition dependent, and change even for one strain, when conditions vary.

It can be summarized that there exists a possibility of survival and even growth of microorganism population on treated crops, but no risk is anticipated due to the fact that *B. amyloliquefacient* is a non-pathogenic, ubiquitous microorganism, prevalent in the microflora of different environmental compartments and media. This was further demonstrated in numerous studies with the strain *B. amyloliquefaciens* QST713 (formerly classified as *B. subtilis* QST 3) which demonstrated absence of toxicity, pathogenicity, and infectivity. Even if an initial growth of *B. amyloliquefaciens* is observed, it is meaningless, since the population will stabilize of decrease, due to the outrient competition, antagonism and environmental conditions.

Report: KIIM 6.3/06 – M.S., M.S., agent Bacillus amyloliquefaciens and 1-methyl cyclopropens on the control of postharvest diseases and maintenance of fruit quality, published report Crop Prot, 30, 173-178
M-518664-01-1

Abstract: Efficacy of biocontrol agent Bacillus daylolique faciens PPCB004 was evaluated on the control of anthracnose and phornopsis to in 'Solo' papaya pre-theated with 1 methyl cyclopropene (100 mL) (1- MCP) during storage. This reatment was compared to the untreated control, commercial treatment (washing incomorinated water), standalone CMCP and PP B004 treatment. Although fruit pre-treated with 1 MCP delayed the ripening (109% yellow) after cold storage by 9e10 d, it showed higher incidence and severity of anthracnose and shomops rotation the fruit subjected to commercial treatment. Application of PPCB004 after 10MCP pro-treatment (1-MCP + PPCB004) reduced the anthracnose and phornopsis incidence and severity after cold storage (10°C, 85% RH for 14 d) and appening at 25°C. The 1 MCP PPCBO04 treatment helped to retain the fruit firmness, overall quality and uniform yellow skin (100%) and flesh colour after ripening. The PPCB004 was effectively recovered from spindaloge PPCB004 and 1-MCP + PPCB004 treated fruit after cold storage and apening. The CPCB004 population showed an increase by 1 log units after ripering in \(\P-MCP\)+ PPCB004 reated truit. After ripering the recovery of PPCB004 population was higher 0.7 be units) in 1 MCP PPCB004. The total recovery of fungal population on the frait surface after ripening was lower in 1-MCP + PPCB004 and standalone PPC\$004 Coated fruit. It can be concluded that application of B. amyloliquefaciens PPCB004 with 1-MCP profreated papaya (at 25-30% skip yellow stage) can significantly reduce disease incidence associated with 1-MCP treatment. This treatment has the potential for commercial application in ythe 'organic' papayacyndustry ₽

Report: FIM 6(3/07 – 100

Abstract: The potential for using Ptenia guilliermondii BCC 5389 or Bacillus subtilis ABS-S14 by themselves or incombination for the control Penicillium digitatum in citrus, and their effects on postharvest quality of fruit was investigated. The percentage of disease with the combined antagonists was completely inhibited Rapid colonization of P. guilliermondii was observed in the wounds during the first day to 6 days at 25°C, whereas B. subtilis, increased marginally over 3 day. The populations they stabilized for the remaining incubation period. The percentage of spore genination of B. digitatum incubated with all treatments was inhibited by 100%. At concentrations of the combined antagonists of 1x108 CFU/mL, the incidence of green mould was reduced to 0% compared with the pathogen control itself (92.93%) after 5 days of incubation at 25°C. The combination did not impair any of the quality parameters of fruit following incubation at 25°C for 7 days.

Report: KIIM 6.3/08 – (2007) Effect of a biocontrol agent (Bacillus subtilis) and modified atmosphere packaging on postharvest decay control and quality retention of litchi during storage, published report Phytoparasitica, 35, 507-518 M-530513-01-1

Abstract: The efficacy of biological control and two types of modified atmosphere packaging of (MAP) alone and in combinations was evaluated under cold storage as well as simulated market. shelf conditions to control decay and pericarp browning on litchi cv. 'Molean's Red'. Fruits were dipped for 2 min at 15°C in Bacillus subtilis or prochloraz separately, packed in MAP low density polyethylene (LDPE) or polypropylene (PP)], heat sealed and stored at 2°C and 90% r.h. or 18 9 days followed by 2 days at 14°C and 75% r.h. to singulate market-shelf conditions. A commercially adopted sulfur dioxide treatment was included as a comparative control. Equits are at the B. subtilis + PP or prochloraz + PP and stand-alone PP treatment did not show decay or browning. at 2°C. Decay and browning were controlled significantly after 2 days at 10°C in B. subtiffe + PP or prochloraz + PP treatments. However, the prochloraz + PP affected the patural pinkish-red color of the pericarp and gave higher h° (hucongle) values. The stand-alone PP treatment $(\sim 14\% O_2, \sim 5\% CO_2)$ showed 11.3% decay due mainly to Alternary and Cradosporium spp. at 14°C. The effectiveness of the MAP was interroved at 14°C when B. substits was combined with PP, controlling decay and pericare browning and retaining the fruit color and quality. B. substits survived in PP at 2° and 14°C, but not in LDPF. Stand-alone LDPE 3%, O2, ~10% CO2, and combination treatments B. subvilis * DPE or prochoraz * LDPE ailled to control decay and pericarp browning. Higher weast populations were observed in LDPE or <math>B subvilies LDPE at both 2° and 14°C. Candida, Cryptococcits and Lygosaccharonives spip were the precominant yeasts in all LDPE treatments.

IIM 6.4 Further information required

IIM 6.4.1 Non-viable residues

B. subtilis does not produce significant quantifies of extracellular enzymes of coxins and is generally considered to have a low degree of volume of the low degree of volume of

and environmental risk potential of *B. amyloliquefaciens*, and indicate that residual cells of *B. amyloliquefaciens* QST713 may present o certain.

Secondly, the unfavourable environmental conditions prevailing on the leaf surface and dependence of *B. amyloliquefaciens* on organic matter supply are restricting its growth. Pagnarily the low health and environmental risk potential of B. amyloliquefaciens, and its ubiquitous distribution indicate that residual cells of B. apploliquefaciens QST713 may present only a low risk

Secondly, the unfavourable environmental Conditions prevailing on the leaf surface and the
