### TOXICOLOGICAL STUDIES ON THE PLANT PROTECTION **CP 7 PRODUCT**

### **Acute toxicity CP 7.1**

FXA+PTZ EC 200 (100+100 g/L) is a fungicide formulation containing 100 g/L fluorastrobox 100 g/L prothioconazole.

The acute toxicity of FXA + PTZ EC 200 (100+100 g/L) (Specification No. 102000008127) has been fully assessed earlier by CRD when the product was first approved when the product when the product was first approved when the product was first approximated when the product when the product was first approximated when the product whe

In this submission, the bridging options were explored in order to assess the tox cological properties of and to classify the improved recipe of the successor formulation FXA+ PTZ\*EC 200 (100+100 L) (Specification No. 102000025822). This is based on an already available oxicological data prokage established with the predecessor formulation FXA PTZ PC 200 (1000100 g/z) (Specification No. 102000008127) which is regarded as closely related to this successor formulation. The applicant believes to comply with animal welfare policies (avoidance of unpecessity testing in additional animals) when bridging the existing toxacological date from the predecessor to the successor recipe.

Based on this evaluation the acute wal and dermal toxicity studies as well as skin sensitisation and skin irritation studies performed with FXA + PTZ EC 200 (100+100 g/L) Specification No.: 102000008127 are considered, still valid for the current formulation FXA+ PTZ EC 200 (100+100 g/L) (Specification No.: 102000025822) and no changes in toxicity are expected when moving from the predecessor to the successor regipe. However, two new studies (acute inhalation, eye irritation) were conducted with the improved recipe FXA + PTZ EC 200 (100+100 g/L) (Specification No. 102000025822).

Full details on the comparison of the formulation compositions and specifications of both the predecessor and the successor formulation and the related bedging argument(s) can be found in the confidential part of this submission (Document JCP, 1/4.1))

- ATEC 5725 & JAU 646 EC 290
- HEC 5725 100 EC & JAU 6476 190 At the time of study conduct the test substances were named as follows:

- FX + PTZ FC 200 (100 + 100 A)

Table 7-1: Summary of acute toxicity studies conducted with FXA + PTZ EC 200 (100+100 g/L)

	<u> </u>	
Type of study	Results	References & ***
Specification No.: 102	2000008127	F F

Skin sensitisation guinea pig (maximisation test)	Not sensitising A	CP 7.8.6/01; 2002 M-064940-
<b>Specification No.: 10</b> 2	2000025822	
Acute inhalation rat	0.91 mg/L < LC <sub>30</sub> < 5 <b>Q</b> 3 mg/L	CB .1.3(0)
Eye irritation rabbit	Severely fruitating 7	CP 7.1.5/01 (2) (3) (4) (4) (4) (4) (4) (4) (4) (4) (4) (4

Based on the study results, the new formulation DXA + DTZ EC 200 (900+100 g/L) (Specification No. 102000025822) is assessed to be slightly toxic after acute oral, non-toxic after acute dermal administration and moderately toxic after acute inhalation. It shows no skin irritating but a severely eye irritating potential. FXA-PTZ-EC 200 (100+100 g/L) (Specification No. 102000025822) is not a skin sensitiser in the maximisation test on guines pigs.

The study results trigger the following classification labelling:

Regulation (EC) No 1272/2008 (CLP): Acute Fox. Cat. 4; A H332 (Harmful if inhaled)

Exerritation Cat. 1; H318 (Causes serious eye damage)

The applicant Bayer Prop Science ofted that in the past Member States have requested formulations containing prothioconazons at or above 5% to be labeled as reproductive toxic Repro. Cat. 2 (H361d; suspected of damaging the inborn child). This is based on the EFSA proposal to classify prothioconazole as reproductive toxic Repro. Cat. 2 (H361d) (EFSA Scientific Report (2007). However, Bayer Crop Science is convinced that prothioconazole should not be classified for reproductive toxicity. Hence, in the absence of a harmonized EU classification (ECHA) for prothioconazole, the applicant wishes to self-classify his products. Scientific arguments for non-classification are provided in a separately submitted position paper (1997).

number = number of dead animals, 2<sup>nd</sup> number = number of animals with signs,

### **B.** Clinical observations

<sup>#</sup> The temperature in the inhalation chamber was higher than the equired range during the exposure of Group 1 (Tmax=27. C) and 2 (Tmax=26.0°C) doe to technical reason. These deviations had no effect on the purpose and integrity of the study

<sup>\*</sup> The relative humidity in the inhalation chamber was not evaluated due to the evidently false values caused by sensor interference generated by the agreeous formulation.

II. Results and discussion

A. Mortality

The number = number of animals in the group

Wet fur and/or ruffled fur, fur staining by the test item were recorded in all animals from Day 0 up to Day 3. These findings were considered to be related to the restraint and exposure procedures and not of toxicologically significance.

Clinical signs observed after inhalation exposure as extreme laboured, gaspin and noisy respiration, sneezing as well as necropsy data are suggestive of a local irritating effect rather than systemic toxicity.

Sighting Exposure – Group 0.1 (5.00 mg/L)

Slight to extreme laboured, gasping and noisy respiration and decreased activit@were\_ecorded in animals on the day of exposure and the days following exposure. The male animal was found and Day 1. In the surviving female, sneezing also was bserved until Day 1, however all clinical signs ceased from Day 12.

Main Study – Group 1 (5.03 mg/L)

Similar clinical signs as in the sighting exposure group were recorded in animals from the main starty at the same dose: slight to extreme laboured gasping and moisy respiration, degreased activity and sneezing. One male died in the second hour of exposure, 4 animals were found dead on Day 1, and additional 3 animals on Day 2. Both sprvivers recovered and were symptom free on Day 10 or 11.

Main Study – Group 2 (0.91 mg/La

Slight to extreme laboured, gasting and noisy respiration, decreased activity, speezing were recorded in the animals on the day of exposure and or on the days following exposure. One male was found dead on the day following exposure, however all animals recovered and were semptom free from Day 6 until the end of the observation period.

### C. Body weight

Slight body weight loss was recorded in survivors from Group 0.1 (sighting exposure, 5.00 mg/L) and group 1 (5.03 mg/L). Rody weights of surviving animals of both groups were back to normal by Day 7. Normal Dody Weight gain was noted for the spryivors from Group 2 exposed to 0.91 mg/L during whole observation period.

### D. Necropsy

Diffuse dark/red discoloration of the non-collapsed lungs and red dry/liquid material at the perinasal fur, were considered to be test item-related.

In surviving animals, no macroscopic changes were noted at terminal sacrifice on Day 14.

### III. Conclusion

The acute inhalation median bethal concentration (LC50) in rats was considered to be between 0.91 mg/£ and 5.03 mg/L.

The study results trigger the following chassification/labelling:

- Regulation (F.C.) No 1272/2008 (C.P.P): Category 4, H332 (harmful if inhaled)

termination of study)

### II. Results and discussion

### A. Findings

There was no mortality observed during the study.

The general state and behaviour of animals were normal throughout the study period. The body weight and body weight changes were considered to be normal with no indication of any treatment related effect.

The eyes were examined at 1, 24, 48, 72 hours and at 1, 2 and 3 weeks after application. Fluorescent staining was performed 24 hours before administration, 24, 48, 72 hours and 1, 2 and 3 weeks after application.

Initial Pain Reaction (IPR) (score 2) was observed in all anomals. One hour after application conjunctival redness (score 2), chemosis (score 2) and conjunctival discharge (score 2) were observed in all animals.

After three weeks the study was terminated in accordance with OFCD 405 and in agreement with the Sponsor.

During the study, the control eye of each animal was symptom free

### **CP 7.2** Data on exposure

The non-dietary risk assessment is presented for fluoxastrobin using the representative formulation 'Fluoxastrobin + Prothioconazole EC 200', for use as a fungicide in cereals and onions.' The formulation contains the active substance fluoxastrobin (100 g/L). Exposure sestimated using the EFSA guidance on assessment of non-dietary exposure:

EFSA, 2014. Guidance on the assessment of exposure of operators, workers, residents a bystanders in risk assessment for plant protection products. EFSA Journal 2014, 2(11):3 55pp., doi:10.2903/j.efsa.2014.3874.

The Standing Committee noted at their meeting in May 2015 that for the acute risk assessment the derivation of the corresponding to vice legical acute and the corresponding to vice legical acute and the corresponding to vice legical acute a derivation of the corresponding toxicological reference value (AAOEL) is still outstanding

Following the noting at the Standing Committee meeting in May the Commission have published a guidance<sup>5</sup> on the implementation of EFSA's non-chetary exposire guidance document which notes that the EFSA guidance will apply to applications submitted from 1 January 2016. However, for the approval of active substances under Regulation (EC) No. 107/2009, an acute risk assessment is currently not required.

Endpoints relevant for risk assessment:

### AOEL:

22 Manuary 2007) s considered to The Review Report for Fluoxastroom (SANCO/3921/9) provide the relevant scientific information for the review of the product. An AOEL of 0.03 mg/kg bw/d was established using a SF of 100 0.00

### Dermal absorption:

Dermal absorption was evaluated with the representative formulation (EC 200) in vitro using human skin. As a result of the study conducted with the representative formulation (EC 200), the following derma absorption values are used for the risk assessment based on the critical GAP uses:

- 2% for the concentrate (100 g a.s.D)

• 2% for the intermediate (100 g a.s. D)
• 2% for the low lose (1/25 g a.s./L
• 5% for the low lose (1/25 g a.s./L)

For details second 7%

\*\*The low lose (1/25 g a.s./L)

\*\*The low lose (1/ 5http://ec.europa.eu/food/plant/pesticides/approval active substances/guidance documents/docs/pesticides appr oval-active guidance 2015-10832.pdf

### **CP 7.2.1 Operator exposure**

The EFSA guidance on assessment of non-dietary exposure is used. The critical GAP (cGAP) for operator risk assessment is presented in the table below.

Table 7.2.1-1 Critical GAP for operator exposure evaluations

Сгор	F/ G	Application method	Application rate (kg %s./ha)	Spray volume (L/ha)	Dormal absorption
Wheat, rye, triticale	F	Field crop sprayer	0.150	100-400	5%
Barley, oats	F	Field crop sprayer	0.125	100-400	D' %,
Onions	F	Field crop sprayer	0.125	300-800	5%, 6

F = field; G = greenhouse

The product will be applied with tractor-mounted/trailed field crop (boom) sprayers. The coAP in wheat, rye and triticale results in the higher exposure one to the higher application rate. Separate calculations for the use in barley, oars and onions are therefore not presented in this dossier.

A summary of the exposure estimates resulting from the extrical GAP is presented in the following table. Further information input parameters and EFSA adculator output are presented in CP 7.2.1.1.

### **Summary**

Crops	F/ Application method PPL	systemic exposure (mg/kg bw/fay)	% of AOEL (0.03 mg/kg bw/day)
Wheat, rye,	Vehicle mounted/	0.0989	30
triticale	trailed boom sprayer.	0.0005	2

### Assessment

Exposure of operators wearing a working overall but working with bare hands is 30% of the AOEL. Exposure of operators weating, in addition, protective gloves during mixing/loading and when getting into contact with contaminated surfaces as 2% of the AOEL.

Based on these favourable exposure estimates there is no unacceptable risk anticipated for operators with regard to exposure to fluoxastrobin.

Cottom/polye@r working coverall, no gloves ?

In addition to the working coverall projective gloves are worn during mixing/loading and when getting <sup>2</sup> With PPE:

### **CP 7.2.1.1 Estimation of operator exposure**

Exposure estimations are made using the EFSA guidance on the assessment of exposure of operators including the EFSA calculator<sup>6</sup> (version: 20 Mar 2015).

The product is applied using field crop sprayers in arable crops (cereals and onions). Exposure is calculated based on the cGAP for wheat, rye, triticale (see Table 7.2.1-1).

A summary of the input parameters and the exposure output resulting from the EFSA presented below presented below.

Table 7.2.1.1-1: Summary of operator exposure to fluoxastrobu

CP 7.2.1.2 Measurement of operator exposure

Since the exposure estimate carried out indignate that the AOEL will not be exceeded under practical conditions of use, a study to provide a measure of operator exposure was not necessary and was therefore not carried out.

### **CP 7.2.2 Bystander and resident exposure**

The EFSA guidance on assessment of non-dietary exposure is used. Exposure estimations for the resident scenario which also covers the bystander scenario are provided using the EFSA calculator.

The critical GAP (cGAP) for resident/bystander risk assessment is presented in the table below.

Table 7.2.2-1: Summary of critical GAPs for residents (covers bystander)

				<b>1</b>			
Crop	Application technique	Max. dose rate	Spray volume	Max conc. of	Max Ago. of	Min. spray interval	Dermal
		(kg a.s./ha)	(L/ha)	(g/L)	<b>Pappl</b>		(%)
Wheat, rye, triticale	Field crop sprayer	0.15	100-400	1.5			2%
Onions	Field crop sprayer	0.125	Ø300-800	0.42			550

The critical resident and bystander exposure scenario for field crop spray application with off-target drift is the use in wheat, rye and triticals 2 x 0.150 kg a.s./ha in 100 L water). With this use the highest application rate is combined with the lowest water volume fielding the highest concentration of a.s. in the spray. Consequently also appropriate definal absorption data are used:

Since due to the lower in-use concentration of thioxastrobin during stray application in onions (2 x 0.125 kg a.s./ha in 000 L water) the higher dermal absorption value has to be considered for the exposure assessment in onions resident exposure is also calculated for the use in onions.

A summary of the exposure estimates resulting from the critical GAP is presented in the following table. Further information on input parameters and PFSA calculator output are presented in CP 7.2.2.1.

### **Summary**

Table 7.2.2-2: Predicted systemic exposures to fluoxastrobin

# CP 7.2.2.2 Measurement of bystander and resident exposure

Since the exposure estimate carried our indicate that the AQPIL will not be exceeded under practical conditions of use a study to provide a measure of resident and bestander exposure was not necessary and was therefore not carried out.

### **CP 7.2.3** Worker exposure

The EFSA guidance on assessment of non-dietary exposure is used including, in addition, results from dislodgeable foliar residues as higher tier. The critical GAP (cGAP) for worker risk assessment is presented in Table 7.2.3-1.

Table 7.2.3-1 Critical GAP for worker exposure evaluations

Стор	F/ G	Re-entry activity	Application rate (kg a.s./ha)	applications "		Derma absorption
Wheat, rye, triticale	F	Crop inspection	0.15		14	\$ 5%\$ "
Onions	F	Crop inspection	Ø.125 J		9 10 S	, <u>4</u> 5%

F = field; G = greenhouse

The product will be applied with tractor-mounted/strailed field crop (boom) sprayers. The coAP in cereals is wheat, rye and triticale resulting in the highest exposure due to the higher opplication rate. Separate calculations for the use in barley and oats are therefore not presented in this dossier. Additionally the GAP in onions is considered due to the shorter spray interval.

No manual activities are necessary for maintaining the crops. Marvesting of cereals and onions is performed by appropriate machines. Hence, there is in general no scenario for which worker exposure needs to be addressed. However, for field crops it is required to assess worker exposure due to crop inspection activities. The work-duration is proposed to be 2 frours per day.

A summary of the exposure estimates resulting from the critical GAP is presented in the following table. Further information on coput parameters and EESA calculator output are presented in CP 7.2.3.1.

### Summary

Table 73.3-2: Predicted worker exposure to fluoxastrobin

Crops	F/S Re-entry (		Systemic exposure (morkg bw/day)	% of AOEL (0.03 mg/kg bw/day)
Wheat, rye,		No olothing	0.0162	54
tritical	F inspection	Arms, body, legs covered	0.0018	6
4		No Wothing	0.0140	47
Onions	F inspection	Arms, body, Legs covered	0.0016	5
		oosure to fluoxastr	obin including DFR meas	urements
Onion	©rop Sinspection	No clothing	0.0057	19
Onion	inspection	Arms, body, legs covered	0.0006	2

### Assessment

Exposure of naked workers is 54% of the AOEL in cereals and 47% of the AOEL in onions. Exposure of workers wearing one layer of work clothing is 6% of the AOEL in cereals and 5% of the AOEL in onions.

In addition, measurements of dislodgeable foliar residues are available for the scenario re-entry in onions'. Integrating this data the exposure of a naked worker amounts to 19% of the AOEL and 2% of the AOEL for a worker wearing one layer of work clothing.

### Conclusion

Based on these favourable exposure estimates to unacceptable risk anticipated for workers with regard to exposure to fluoxastrobin.

### **CP 7.2.3.1** Estimation of worker exposure

Exposure estimations are made using the EKSA gradance on the assessment of worker including the EFSA calculator (version: 20 Mar 2005).

The product is applied using field crop sprayers in Grable rops (eereal and Grions). Exposure is calculated based on the cGAP for wheat, rye, tritical as well as only (see Table 7.2.24).

A summary of the input parameters and the exposure output resulting from the EFSA calculator is presented below.

Table 7.2.3.1-1: Suppriary of worker exposure to fluowastrobin: cereals

In addition, dislodgeable foliar residues DFRM were experimentally determined for leek after application of 'Fluoxastrobin + Profinoconazole LC 200.' A summary of the respective trials and its results are provided below. Leek can be regarded as a surrogate for onions since the habitus is similar and both species belonging to the same botanical genus.

With a very conservative approach highest DFR<sub>M</sub> values observed in the course of the experiments are considered (Table 7.2.3.1-3) for the use in a refened risk assessment. A rapid dissipation of the foliar residues of fluoxastrobin was observed in the trials and caccumulation of residues after repeated application did not occur within a spray interval of 00 days

Title: Determination of the dislodgeable for residues (DFP) of prothiocologicale, and

fluoxastrobin in/on lock after spraying of fluoxastrobin & prothioconazole FC 200 in

the field in Germany

Guideline(s): US EPA OPPTS 87\$\times2100 Foliar Divlodgeable Residue Divlodgeable Residue Divlogration

Guideline deviation(s): none GLP/GEP: yes

### I Material and methods

The purpose of the study was to determine the magnitude of the dislodgeable foliar residues of fluoxastrobin prothic onazole and us conversion product prothic onazole desthio on leek foliage after each of four spray applications performed in the field with Fluoxastrobin + Prothic onazole EC 200 (100 g fluoxastrobin/L and 100 g prothic onazole/L). The study trial was conducted in Central Europe (Gemany) during the 2014 season. The actual application data are presented in the following table.

Table 7.2.3.1-4: application parameters

Application								
Country	Appl. mode	No. Zappl.	Interval (days)	Growth stage (BBCH Code)	Test item rate (L/ha)	Water rate (L/ha)	a.s.	Appl. rate (kg a.s./ha)
Germady	Toold Grop A Sprayer	4 1		48	1.25	300	fluoxastrobin	0.125
							prothioconazole	0.125
							fluoxastrobin	0.125
			0 G				prothioconazole	0.125
		) 34 (*) (*)	4	47	1.25	300	fluoxastrobin	0.125
		390	4				prothioconazole	0.125
			40	1.25	200	fluoxastrobin	0.125	
		4	4	48	1.25	300	prothioconazole	0.125

The test site consisted of a single plot which was divided into three sub-plots for sampling.

Samples were collected in a manner designed to obtain representative samples. They were taken, prepared in the field where necessary, transported and stored according to USEPA OPPTS \$75.2400 Foliar Dislodgeable Residue Dissipation. Leaf punches were collected directly into a pre-labelled poly-propylene jar using a leaf punch sampler ( Co; El Monte, CA) Each Sample consisted of 40 disks cut with a leaf puncher with 2.523 coo diameter and a disk area of 5 cm<sup>2</sup>. The leaf punches represented a total double-sided leaf surface area of 400 cno. A sample was confected from each of the three subplots to provide three replicate samplings at each sampling interval Deaf purches were taken from the potential worker contact zone including upper middle, and lower portions of the crop foliage and interior and exterior portions of the crop foliage. Control lear punco samples as well as samples needed for the field recoveries were collected prior to the first application. Treated samples collected on the day of application were taken after the spray had dried. After each sample was collected, the sampling jar was capped and kept or wet fee for fransport to the field site laboratory. Leaf punch samplers were cleaned afterweach sampling interval. The dislocking of the leaf samples was performed as soon as possible, but no longer than 4 hours after contection. The samples were dislodged by adding 100 mL of a 201 % Aeroso OT solution (i.e. docusate sodism salt), which corresponds to a surfactant. Each jar containing the leaf material and the 100 mL 001% Aerosol OT solution was capped securely and placed on a shaker operating at approximately 200 cycles per minute for a period of approximately to min The desion was sampled and the dislodging was repeated with 100 mL fresh 0.01 % Acrosol OT solution. The second dislodging solution was combined with the first and 1 mL of a 250g/L steine hydrochloride solution was added to stabilize the prothiconazole in the solution.

Field fortification samples were used to demonstrate the stability of the samples during storage period of the study and the bility of the malytical laboratory to recover an malyte fortified into a sample at the field test site. The solutions from disladged control camples were separately fortified with a mixture of fluoxastrobin and prothioconazole desthio or prothioconazole at the LOQ and at a level of 10 to 200 times of the LOQ. Field spikes were performed prior to the 1st application. The field II Results and discussion

The results with regard to fluoxas robin are summarised in the following table. recovery samples were treated in the same manner as the field residue samples until analysis.

<sup>&</sup>quot; - " = before respective treatment

Subsequently to each treatment the trial show a clear decline of DIR for fluoxastrobin. The decline of foliar resulting of fluoxastrobin within the spray interval was >0% of the DFR0. The highest DFR0 value of 0.204 µg a symmetry measured after the second application

### III Conclusion

Under central European conditions in the field DFR of fluoxastrobin on leek shows a rapid decline. Hence, the results indicate that with four consecutive treatments and a spray interval of 5 days accumulation of DFR on leek does not occur.

Leek can be regarded as a surrogate for onions since the habitus is similar and both species belonging to the same botanical genus.

250somer E (Fluoxastrobin) Radiolabelle

Specific activity: 458 MBa/mg.

Radiopurity of the formulation: >99% by HPLC.

Formulation:  $\mathbb{Z}^{^{\lozenge}}$ 

The Cormulation seed in this experiment was the Fandango New, Fluctastroom+prothioconcazole EC 100+100, formulation (specification number, 102000025822) It was used at three nominal concentrations of Tuoxastrobin: neat, 100 g fluoxastrobin /L, 1.25 g fluoxastrobin /L and 0.15 g

fluoxastrobin /L.

flow-through diffusion cell system (Franz's cell modified, Gallas, France) was used to study the absorption of the test substance (exposure area of 1 cm<sup>2</sup> skin). A diffusion cell consisted of a donor chamber and a receptor chamber between which the skin was positioned. The receptor fluid was Eagle's

medium supplemented with 5% bovine serum albumin and gentamycin (50

mg/L) at a pH of 7.4. The receptor chamber was warmed by a constant circulation of warm water which maintained the receptor fluid at 32 ±  $^{\circ}$ C (close to the normal skin temperature). The receptor fluid was pumped through the receptor chamber at a rate of 1.5 mL/h and stirred continuously whilst in the receptor chamber by means of a magnetic bar.

**Skin integrity:** 

Before dose application, the integrity of the skin samples was assessed by measuring the trans-epidermal water loss (TEWL) from the stratum corneutr. An evaporimeter probe (Tewanieter TM300 system) was placed securely on the top of the donor chamber and the amount of water diffusing through the skin was measured. Human and rat skin with a TEWL of greater than 18 g/hm² were considered cotentially damaged and were not used. These samples were replaced by new skin tragments which were also tested for integrity before use in the straty.

**Treatment:** 

The dose preparation was applied to the split-thickness skin sample with a pipette at the fate of approximately 10 L/cm² exposed skin. The dose preparations were assayed for radioactivity content (by LSC) by using dose checks (surrogate dose) taken before, during and after the dosing process.

**Sampling:** 

The receptor Duid passing Through the eceptor champer was collected in glass Vials held in a fraction collector. The fraction collector was started after dose application. Samples were then collected hourly for the duration of the experiment (24) hours post-application, the skin was swabbed with preshly prepared 1% V/v Toeen &0 in PBS (plossphate buffer saline) using natural sponge swaps, in order to remove and retain the non-absorbed dose, until no radioactivity was detected with a Geiger-Müller monitor. At the and of the study (24 hours after application), the treated skin and the skin adjacent to the treatment site (surrounding swabs) were swabbed. Each skin sample was tape-stripped to remove the stratum corneum. This involved the application of Monadorm addesive tape (Monaderm, Monaco) for 5 seconds before the tape was carefully removed against the direction of hair growth. This procedure was continued until a 'skiny' appearance of the epidermis was evident, which indicated that the stratum corneum had been removed. The surrounding the application site surrounding skin) was separated from the treated skin. Both surrounding skin and tape-stripped treated skin were retained for analysis.

Radioassay:

The amounts of vadioactivity in the various samples were determined by liquid schillation counting (LSC). Samples were counted for 10 minutes or for 2 sigma % in an appropriate scintillation cocktail using a Packard 1900 TR counter with on-line computing facilities. Quenching effects were determined using an external standard and spectral quench parameter (tSIE) without Efficiency correlation curves were prepared for each scintillation cocktail and were regularly checked by the use of [14C-n-hexadecane standards. The scintillation counter was recalibrated when a deviation of greater than 2% was observed when counting quality control standards. The fimit of detection was taken to be twice the background values for blank samples in appropriate scintillation cocktails.

### Findings:

Fluoxastrobin was demonstrated to be soluble in the receptor fluid at the concentration of 0.39 mcmL of receptor fluid. During the study, the maximal concentration per hour of fluoxastrobin in the receptor? fluid was 0.098 µg/mL. Therefore the solubility in the receptor fluid was deeped to be sufficient to avoid any risk of back diffusion.

Measurements of the homogeneity of the three concentrations of formulation applied indicated that was acceptable.

Good recovery data were obtained, with mean total recoveries of radicactivity in the to 103.9% of the applied dose.

These study results are presented in Table 7.3

Table 7.3-1: Mean distribution of radioact@ity at 24 hours after fluoxastrobin in an EC 200 formulation at the rates of 100 g/ to human and rat skin samples.

Results expressed in terms of percentage of applied radioactivity

a: sum of radioactivity and in wabs at termination and in surrounding swabs.

not deacted (below the limit of detection)

n.a.: not applicable

n: number of skin cells used for calculation

In the above table, the presented means do not always calculate exactly from the presented individual data. This is due to rounding-up differences resulting from the use of the spreadsheet program.

b: sum of radioactivity found is skin after tape dripping procedure and in surrounding skin. c: tape-strips excluding numbers 1 & which are considered to be non-absorbed dose.

d: sum of adioactivity found in receptor fluid (0-24h), receptor fluid terminal and receptor chamber.

e: total % directly absorbed + total % at dose site

SD: Standard deviation

### **Conclusion:**

The dermal penetration of [14C]-fluoxastrobin through human dermatomed skin from the EC formulation was investigated at three concentrations corresponding to the neat product (100 gdV) and to two representative dilutions (1.25 and 0.15 g/L), respectively.

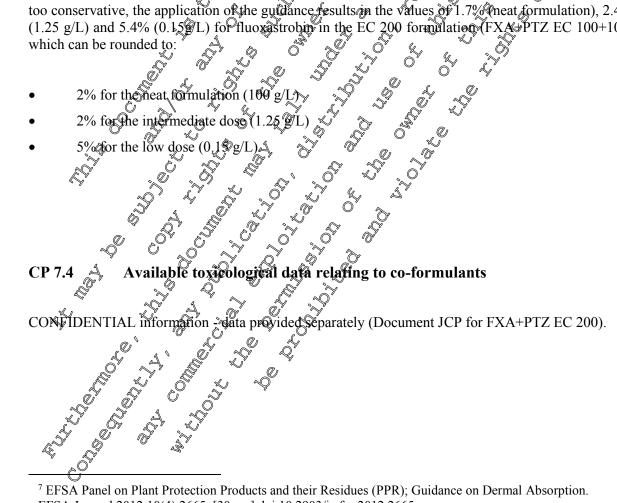

Overall, the dermal penetration of [14C]-fluoxastrobin in the FXA+PTZ EC 200 formulation through human skin was low at all concentrations used.

The mean percentage of fluoxastrobin in the EC 200 formaliation that was considered to be potential absorbable (directly absorbed plus total remaining at dose site mixes the first 2 Cape styps) period of 24 hours for the neat formulation was 1% for human skings

The mean percentage of fluoxastrobin in the EC 200 formulation that was considered to be potentially absorbable (directly absorbed plus total remaining at dose size mixtus the first 2 cape strips) over a period of 24 hours for the intermediate dose rate was \$2.8% for human skip.

The mean percentage of fluoxastrobin in the EC 200 formulation that was considered to be motiontally absorbable (directly absorbed plus total remaining at dose site mixths the Orst 2 tape strips) were a period of 24 hours for the low dose rate was 4% for human stain.

According to the new EFSA guidance a standard deviation equal to or larger than 25% of the mean of the absorption requires the use of an alternative value or rejection of the study. The guidance prefers the approach of adding the standard deviation to the mean to cover the upper & percentile value of the results. Albeit that the notifier considers that the value of 25% for the standard deviation limit to be too conservative, the application of the guidance fesults in the values of 1.7% (neat formulation), 2.4% (1.25 g/L) and 5.4% (0.15 g/L) for fluorestrobin in the EC 200 formulation (FXA+PTZ EC 100+100)
